Blackbody Radiation

Experiment objectives: explore radiation from objects at certain temperatures, commonly known as "blackbody radiation"; make measurements testing the Stefan-Boltzmann law in high- and low-temperature ranges; measure the inverse-square law for thermal radiation.

Theory

A familiar observation to us is that dark-colored objects absorb more thermal radiation (from the sun, for example) than light-colored objects. You may have also observed that a good absorber of radiation is also a good emitter (like dark-colored seats in an automobile). Although we observe thermal radiation ("heat") mostly through our sense of touch, the range of energies at which the radiation is emitted can span the visible spectrum (thus we speak of high-temperature objects being "red hot" or "white hot"). For temperatures below about $600°C$, however, the radiation is emitted in the infrared, and we cannot see it with our eyes, although there are special detectors (like the one you will use in this lab) that can measure it.

An object which absorbs all radiation incident on it is known as an "ideal blackbody". In 1879 Josef Stefan found an empirical relationship between the power per unit area radiated by a blackbody and the temperature, which Ludwig Boltzmann derived theoretically a few years later. This relationship is the **Stefan-Boltzmann law:**

$$S = \sigma T^4 \tag{1}$$

where S is the radiated power per unit area (W/m^2), T is the temperature (in Kelvins), and $\sigma = 5.6703 \times 10^{-8} W/m^2 K^4$ is the Stefan's constant.

Most hot, opaque objects can be approximated as blackbody emitters, but the most ideal blackbody is a closed volume (a cavity) with a very small hole in it. Any radiation entering the cavity is absorbed by the walls, and then is re-emitted out. Physicists first tried to calculate the spectral distribution of the radiation emitted from the ideal blackbody using *classical thermodynamics.* This method involved finding the number of modes of oscillation of the electromagnetic field in the cavity, with the energy per mode of oscillation given by kT. The classical theory gives the **Rayleigh-Jeans law:**

$$u(\lambda, T) = \frac{8\pi kT}{\lambda^4}$$

where $u(\lambda)(J/m^4)$ is the spectral radiance (energy radiated per unit area at a single wavelength or frequency), and λ is the wavelength of radiation. This law agrees with the experiment for radiation at long wavelengths (infrared), but predicts that $u(\lambda)$ should increase infinitely at short wavelengths. This is not observed experimentally (Thank heaven, or we would all be constantly bathed in ultraviolet light-a true ultraviolet catastrophe!). It was known that the wavelength distribution peaked at a specific temperature as described by **Wien's law:**

$$\lambda_{max}T = 2.898 \times 10^{-3} m \cdot K$$

and went to zero for short wavelengths.

The breakthrough came when Planck assumed that the energy of a particular mode of oscillation can only take on discrete values rather than a continuous distribution of values, as in classical physics. With this assumption, Planck's law was derived:

$$u(\lambda, T) = \frac{8\pi hc\lambda^{-5}}{e^{hc/\lambda kT} - 1}$$

Figure 1: Thermal Radiation Setup

where c is the speed of light and $h = 6.626076 \times 10^{-34} J \cdot s$ is the Planck's constant. This proved to be the correct description.

> **Sometimes physicists have to have crazy ideas!**
> *"The problem of radiation-thermodynamics was solved by Max Planck, who was a 100 percent classical physicist (for which he cannot be blamed). It was he who originated what is now known as modern physics. At the turn of the century, at the December 14, 1900 meeting of the German Physical Society, Planck presented his ideas on the subject, which were so unusual and so grotesque that he himself could hardly believe them, even though they caused intense excitement in the audience and the entire world of physics"* From George Gamow, *"Thirty Years that Shook Physics, The Story of Quantum Physics"*, Dover Publications, New York, 1966.)

Safety

The Stefan lamp and Thermal cube will get very hot - be careful!!!

Thermal Radiation rates from Different Surfaces

Equipment needed: Pasco Radiation sensor, Pasco Thermal Radiation Cube, two multimeters, window glass.
   Before starting actual experiment take some time to have fun with the thermal radiation sensor. Can you detect your group mates? What about people across the room? Point sensor in different directions and see what objects affect the readings. **These exercises are fun, but you will also gain important intuition about various factors which may affect the accuracy of the measurements!**

1. Connect the two multimeters and position the Sensor as shown in Fig. 1. The multimeter attached to the cube will be reading resistance in ohms while the one attached to the infrared Radiation Sensor will be reading voltage in millivolts. Make sure the shutter on the Sensor is pushed all the way open!

2. Before turning on the Cube, measure the resistance of the thermistor at room temperature, and obtain the room temperature from the instructor. You will need this information for the data analysis.

3. Turn on the Thermal Radiation Cube and set power to "high" When ohmmeter reading decreases to 40 kΩ (5-20 minutes) reset power switch to "8". (If cube is preheated, immediately set switch to "8".)

> **Important**: when using thermal radiation sensor, make each reading quickly to keep sensor from heating up. Use both sheets of white isolating foam (with the silvered surface facing the lamp) to block sensor between measurements.
>
> **Sensor calibration**: To obtain the Radiation Sensor readings for radiated power per unit area S in the correct units (W/m^2), you need to use the known voltage-to-power conversion factor: $22\,mV/mW$, and the known area of the sensor $2mm \times 2mm$:
>
> $$S[W/m^2] = \frac{S[mV]}{22[mV/mW]} \cdot 10^{-3} \cdot \frac{1}{4 \cdot 10^{-6}[m^2]}$$

4. When the cube has reached thermal equilibrium (the ohmmeter will be fluctuating around a constant value), record the resistance of the thermistor in the cube and determine the approximate value of the temperature using data table in Fig. . Use the radiation sensor to measure the radiation emitted from the four surfaces of the cube. Place the sensor so that the posts on its end are in contact with the cube surface (this ensures that the distance of the measurement is the same for all surfaces) and record the sensor reading. Each lab partner should repeat this measurement.

5. Place radiation sensor approximately 5 cm from the black surface of the Radiation cube and record reading. Place a piece of glass between the sensor and the cube. Does window glass effectively block thermal radiation? Try observing the effects of other objects.

 Use your data to address the following questions in your lab report:

1. Is it true that good absorbers of radiation are good emitters?

2. Is the emission from the black and white surface similar?

3. Do objects at the same temperature emit different amounts of radiation?

4. Is glass an effective block of thermal radiation? List other objects, if you tried them.

Tests of the Stefan-Boltzmann Law

High temperature regime

Equipment needed: Radiation sensor, 3 multimeters, Stefan-Boltzmann Lamp, Power supply.

1. **Before turning on the lamp**, measure the resistance of the filament of the Stefan-Boltzmann lamp at room temperature. Obtain the reading of room temperature from the instructor.

2. Set up the equipment as shown in Fig. 3. VERY IMPORTANT: Make all connections to lamp when power is off. Turn power off before changing/removing connections. The voltmeter (multimeter) should be directly connected to the binding posts of the Stefan-Boltzmann lamp. NOTE: even through the power supply displays both current and voltage, it is more accurate to make these measurements using two independent multimeters.

3. Place the Thermal Sensor at the same height as the filament, with the front face of the Sensor approximately 6 cm away from the filament (this distance will be fixed throughout the measurement). Make sure no other objects are viewed by the Sensor other than the lamp.

4. Turn on the lamp power supply. Set the voltage, V, in steps of one volt from 1-12 volts. At each V, record the ammeter (current) reading from the lamp and the voltage from the Radiation Sensor. Calculate the resistance of the lamp $(R = V/I)$ and determine the temperature T of the lamp from the table shown in Fig. 4.

Figure 4: Table of Tungsten's Resistance as a function of temperature.

Sample table for experimental data recording:

Data($\pm$ error)			Calculations		
$V((volts)$	$I(amps)$	$Rad(mV)$	R(ohms)	$T(K)$	$T^4(K^4)$
1.00					
. . .					

In the lab report plot the reading from the Radiation Sensor (convert to W/m^2) versus T^4. Make a linear fit according to the Stefan-Boltzmann Law and report what value of slope you obtain. How does it compare to the actual Stefan's constant?

Don't be alarmed if the value of slope is way off from Stefan's constant. The Stefan-Boltzmann Law as stated in Eq.(1) is only true for IDEAL black bodies. For other objects, a more general law is: $S = A\sigma T^4$, where A is the absorptivity. $A = 1$ for a perfect blackbody. $A < 1$ means the object does not absorb (or emit) all the radiation incident on it (this object only radiates a fraction of the radiation of a true blackbody). The material lampblack has $A = 0.95$ while tungsten wire has $A = 0.032$ (at $30°C$) to 0.35 (at $3300°C$). Comparing your value of slope to Stefan's constant, and assuming that the Stefan-Boltzmann Law is still valid, what do you obtain for A? How does it compare for the value of tungsten? What else could be affecting this measurement?

Low temperature regime

Equipment needed: Radiation Sensor, 2 Multimeters, Thermal Radiation Cube.

1. Set up equipment as shown in Fig. 5. The Radiation Sensor should be pointed directly at the center of one of the better radiating surfaces (the black or white surface). The face of the Sensor should be parallel with the surface of the cube and about 3-4 cm away.

2. Shield the Sensor from the Cube using the reflective heat shield, with reflective side towards cube.

3. Turn on the Cube and set power switch to 10.

4. When the thermistor resistance indicates the temperature is about $12°C$ above room temperature, turn the power down so that the temperature is changing slowly. Read and record the thermistor reading R_{th} and the Radiation Sensor reading Rad. The readings should be taken as simultaneously as possible, while **briefly** removing the heat shield. Take care that the position of the sensor remains fixed during all the measurements.
Figure 5: Low-Temperature Stefan-Boltzmann Setup

5. Replace the heat shield, and turn Cube power back up to 10. When the temperature has risen an additional $12 - 15°C$, repeat measurements of step 4). Repeat this procedure at about $12 - 15°C$ intervals until maximum temperature of Cube is reached. Be patient with this measurement- you have to wait for the temperature to change. It might help to have one partner read the thermistor reading while the other reads the Radiation Sensor simultaneously.

Sample table for experimental data recording:

Data± error			Calculations
$R_{th}(\Omega)$	$Rad(mV)$	$T°C$ and K	$T(K)^4 - T(K)^4_{room}$

In your lab report, plot the Radiation Sensor reading versus $(T^4 - T^4_{room})$. The reason we need to subtract room temperature radiation intensity is that at lower temperatures the radiation from the Sensor itself must be taken into account. This means: $S_{det} = \sigma T^4_{det}$. We assume the Sensor stays at room temperature (if you keep the Sensor covered in between readings). Therefore, $S = S_{cube} - S_{det} = \sigma(T^4 - T^4_{room})$. Therefore, plot your radiation readings versus $(T^4 - T^4_{room})$. Make a linear fit of this plot and extract a slope. How does this compare to Stefan's constant? What value of A do you find? Is the Cube surface an ideal blackbody? Remember: there may be error because the conversion to radiant intensity (W/cm2) from mV reading is only an approximate value.

Test of the inverse-square law

Equipment needed: Radiation sensor, Stefan-Boltzmann lamp, multimeter, power supply, meter stick. A point source of radiation emits that radiation according to an inverse square law: that is, the intensity of the radiation in (W/m^2) is proportional to the inverse square of the distance from that source. You will determine if this is true for a lamp.

1. Set up the equipment as shown in Fig. 6. Tape the meter stick to the table. Place the Stefan-Boltzmann lamp at one end, and the Radiation Sensor in direct line on the other side. The zero-point of the meter stick should align with the lamp filament. Adjust the height of the Radiation Sensor so it is equal to the height of the lamp. Align the system so that when you slide the sensor along the meter stick the sensor still aligns with the axis of the lamp. Connect the multimeter (reading millivolts) to the Sensor and the lamp to the power supply.
Figure 6: Inverse Square Law Setup

2. With the LAMP OFF, slide the sensor along the meter stick. Record the reading of the voltmeter at 10 cm intervals. Average these values to determine the ambient level of thermal radiation. You will need to subtract this average value from your measurements with the lamp on.

3. Turn on the power supply to the lamp. Set the voltage to approximately 10 V (DO NOT EXCEED 13 V!). Adjust the distance between the Sensor and lamp from 2.5-100 cm and record the Radiation Sensor reading (in mV). **Before actual experiment think carefully about at what distances you want to take the measurements. Is taking them at constant intervals work well? At what distances you expect the sensor reading change more rapidly?**

4. Make a plot of the corrected radiation measured from the lamp versus the inverse square of the distance from the lamp to the sensor ($1/x^2$). Make a linear fit of this plot. How good is the fit? Is this data linear over the entire range of distances? Comment on any discrepancies. After you fit your data to a linear plot, give the errors for the values of slope.

5. Does radiation from the lamp follow the inverse square law? Can the lamp be considered a point source? If not, how could this affect your measurements?
